

CS304: Automata and Formal Languages

Lec 9

Kleene's Theorem

Rachit Nimavat

August 21, 2025

Outline

- 1 Recap
- 2 Regular Languages
- 3 Proving Kleene's Theorem
- 4 Proving Kleene's Theorem
- 5 Post-Kleene Theorem

Deterministic Finite Automata (DFA)

Formal Definition

DFA is a 5-tuple $A = (Q, \Sigma, \delta, q_0, F)$

'symbol'

Q

Σ

δ

$q_0 \in Q$

$F \subseteq Q$

description

finite set of states

underlying finite alphabet

transition function between states

start state

accepting states

Deterministic Finite Automata (DFA)

Visualizing DFA

State Diagram is the intuitive way we visualize and work with DFAs

Conventions:

States Q are circles

Start state (q_0) has an incoming arrow labeled start

Accepting states (F) are double circles

Transitions (δ) are arrows between states, labeled with input symbols from Σ

Our DFA for $L = 0^*1$:

Non-Deterministic Finite Automata (NFA)

Visualizing NFA

State Diagram is the intuitive way we visualize and work with NFAs

Conventions:

States Q are circles

Start state (q_0) has an incoming arrow labeled start

Accepting states (F) are double circles

Transitions (δ) are arrows between states, labeled with input symbols from Σ

Our NFA for $L = 0^*1$:

NFA vs DFA

NFA

$$N = (Q, \Sigma, \delta, q_0, F)$$

$$\delta : Q \times (\Sigma \cup \{\varepsilon\}) \mapsto 2^Q$$

Multiple Transitions. Possibly multiple outgoing arrows for same symbol

Zero Transitions. Possibly no outgoing arrow for a symbol (that path "dies" *has license to kill*)

ε -Transitions. Can change state without consuming an input symbol

Theorem 1.1

A language is recognized by an NFA if and only if it is recognized by a DFA.

DFA

$$D = (Q, \Sigma, \delta, q_0, F)$$

$$\delta : Q \times \Sigma \mapsto Q$$

No such powers!

-ENGLISH**

Regular Language

Defn: A language L is called a regular language if and only if there exists a regular expression R that describes it: $L = L(R)$

Theorem 2.1 (Kleene's Theorem)

All these definitions are equivalent:

- $\exists$ a DFA D such that $L = L(D)$
- $\exists$ an NFA A such that $L = L(A)$
- $\exists$ an RE R such that $L = L(R)$

Kleene's Theorem: $RE \implies NFA$

Step-by-step algorithm to convert an RE to an NFA

Primitive Regular Expressions (Base case):

RE	NFA
a (where $a \in \Sigma$)	 <pre> graph LR start((start)) -- a --> q1(((q1))) style start fill:#d1c4e9,stroke:#333,stroke-width:1px style q1 fill:#d1c4e9,stroke:#333,stroke-width:1px,stroke-dasharray: 5 5 </pre>
ϵ	 <pre> graph LR start((start)) --> q0(((q0))) style start fill:#d1c4e9,stroke:#333,stroke-width:1px style q0 fill:#d1c4e9,stroke:#333,stroke-width:1px,stroke-dasharray: 5 5 </pre>
$\emptyset$	 <pre> graph LR start((start)) --> q0((q0)) style start fill:#d1c4e9,stroke:#333,stroke-width:1px style q0 fill:#d1c4e9,stroke:#333,stroke-width:1px </pre>

Kleene's Theorem: $RE \implies NFA$

Step-by-step algorithm to convert an RE to an NFA

Combining Machines (Inductive step):

- $R_1 + R_2$ (union)

$R_1 + R_2$

Kleene's Theorem: $RE \implies NFA$

Step-by-step algorithm to convert an RE to an NFA

Combining Machines (Inductive step):

- $R_1 R_2$
(concatenation)

$R_1 R_2$

Kleene's Theorem: $RE \implies NFA$

Step-by-step algorithm to convert an RE to an NFA

Combining Machines (Inductive step):

- R_1^* (Kleene star)

NFA++

We have already shown that $\text{RE} \implies \text{NFA}$.

Observation: An “NFA” where labels of its paths are REs is also an NFA!

Definition 4.1

Consider a finite alphabet Σ and let $\mathcal{R}$ be the set of all Regular Expressions over Σ . An NFA++ is a 5-tuple $A = (Q, \Sigma, \delta, q_0, q_f)$, where

Q : finite set of states

q_0 : single starting state

q_f : single accepting state

$\delta : (Q \setminus q_f) \times (Q \setminus q_0) \mapsto \mathcal{R}$

recall, $\mathcal{R}$ includes the “empty” language $\emptyset$

HW: Formally prove that $\text{NFA} = \text{NFA}++$.

i.e. $\forall \text{NFA } M_1, \exists \text{NFA}++ M_2$ such that $L(M_1) = L(M_2)$.

Notice that the other direction: $\forall \text{NFA}++ M_2, \exists \text{NFA } M_1$ such that $L(M_2) = L(M_1)$ is trivial.

Kleene's Theorem: $\text{NFA}^{++} \Rightarrow \text{RE}$

State Elimination

We'll remove states from NFA^{++} one-by-one until we are left with just the start state q_0 and accept states q_f

Over to the board!

What Now?

We completed one of the most important results of this course: Kleene's Theorem.

Closure Properties: A set is closed under an operation if applying that operation to its elements results in elements that are also in the set

- Integers are closed under addition $\text{int} + \text{int} = \text{int}$
- Integers are closed under division **false!** $3 / 2 = 1.5$
- Real numbers are closed under division **false!** $0 / 0$ is undefined
- Regular languages are closed under union They are regular expressions!
- Regular languages are closed under complementation They are DFAs!

HW: Prove last 2 statements!

Irregular Languages

We've spent all this time defining what regular languages are

But are there languages that are not regular?

Are there languages that a finite automaton cannot solve no matter how many states it has?

Yes! These are called **Irregular Languages**

How do we even prove that for some given language L , there is NO NFA that accepts it?

Pumping Lemma!
